Physical activity and accidental falls in senior center users

Priscila Carneiro Valim-Rogatto
UNIFESP - Universidade Federal de São Paulo, Escola Paulista de Medicina. Depto. de Enfermagem, São Paulo, SP, Brasil

The aims of this observational, cross-sectional study were: i) investigate the prevalence of accidental falls in Senior Citizen Centers (SCC) users and the influence of factors associated with these falls such as age group, sex, civil status, level of education, family/person income, retirement, labor market participation, cognitive status, registration period and activities carried out at SCC, and level of physical activity; ii) estimate the level of physical activity in this elderly population relating to the variables described above as well as the possible association with accidental falls; and iii) analyze the association among level of physical activity and related-factors and/or consequences on the most recent fall (number, daytime and fall location, fracture or injury occurrence, search for medical services and fear of falling). The sample included 350 Senior Citizens from three different SCC from Cuiabá City (Mato Grosso State, Brazil) that answered the Mini-mental State Examination–MMSE and the International Physical Activity Questionnaire–IPAQ short version. The Characterization of Falls Questionnaire was answered only by those elderly who had fallen. Descriptive Statistic, Binary Logistic Regression and Ordinal Logistic Regression by Proportional Odds Model (POM) were used for data analyses (p<0.05) from a 291 elderly sub-sample. About 40% of the elderly suffered falls in the last year. From this group, 45.3% declared to have fallen two or more times in the same period. The predictive model of falls was comprised by the following variables: female gender (OR= 5.12; IC= 2.48–10.56), 75-79 years old age group (OR=3.0; IC= 1.20–7.47), divorced marital status (OR=4.09; IC= 1.27–13.22), and to be pensioner (OR=2.82; IC= 1.20–6.64). Analyzing the level of physical activity (LPA), 38.1% of voluntaries were classified as high level, 49.8% as moderate level and 12.1% as low level. The results of POM indicated that the oldest group showed lower chance to be classified as high LPA (OR=0.78; IC=0.96-2.92) than elderly younger groups. Seniors that do not have a job (OR=0.38; IC=0.22–0.67) and those with low cognitive status (OR=0.31; IC=0.31-0.38) had little possibility to be in high LPA in opposition to the other levels. Regarding to the last fall reported, it was verified that 46.2% occurred in the afternoon, 9.4% resulted in fractures, 70.9% resulted in some sort of injury and 23.9% did not result in any impairments. It was also verified that 54.7% of the elderly suffered outdoor falls, 61.5% did not seek any medical services for the injuries. The search for medical services was associated to the most recent fall with 45.8% of those who fell during the day did report to seek medical services. Also, 15.2% of Fractures occurred during the day. In opposition to the other levels, this group had smaller chance of being classified as high LPA (OR=0.68; IC=0.39–1.18). In conclusion, the study results demonstrate that accidents and related factors influence the level of physical activity in elderly. This has an important public health significance, as the self-reported physical activity level is related to the frequency of falls. Caminhos de prevenção estão indicados, assim como a necessidade de mais pesquisas sobre este tema.

Key-Worlds: Accidental falls; Exercise; Aged; Health services for the aged; Centers of connivance and leisure.
